

PREPARATION BOOTCAMP

< STRINGS />

PREPARATION BOOTCAMP

GAME

OH MY GIT!

In addition to the tasks below, you must go as far as possible in [this game](#).

Work on it as soon as you have a bit of time, or whenever you need a break in your day!

You can also have a look at [learngitbranching](#).

Strings

Task 1.1

Store a long string (such as a sentence), in a variable. Then, print it.

Task 1.2

Print the first character of your string.

Task 1.3

Print the last character of your string.

Task 1.4

Using one line of code, print from the fifth to the tenth character of your string.

Task 1.5

Write a snippet of code to transform your string into lower case.

Your code should work for any non-empty string.

Task 1.6

Write a snippet of code that replaces every "tu" in a string by "ta".

The input `tutu on the tuki-kata` gives the output `tata on the taki-kata`.

Task 1.7

Explain the following code and predict its output. Then, test your prediction by running the code.

```
string = "Hello world!"
position = string.find("a")
print(position)
```

Task 1.8

Can you predict the result of the following snippet of code?

```
p = "abcdefghij"
print(p[::-2][:5][::-1][3:])
```

Task 1.9

Can you break down each step in order to simplify the previous code?

Task 1.10

Write a snippet of code that prints 10 times a given string.

Task 1.11

Debug `print("hello" + 42)`.

```
man ascii
```

CHALLENGE

The challenge uses several notions scattered throughout the subject's exercises. If you don't feel up to it straight away, that's normal. Come back later to try again. You should compare your productions with others and discuss the pros and cons of each solution. The best answers could be presented publicly.

Write a snippet of code that counts the total number of occurrences of the strings "cat", "garden" and "mice" in any string, considering that:

- ✓ each substring can be read left to right OR right to left;
- ✓ matches must be **case insensitive**;
- ✓ you should not bother with overlaps.

For instance, the strings:

- ✓ "the CataCat attaCk a Cat" should return 5;
- ✓ "thE Cat's tactic wAS tO surPRiSE thE mIce iN tHE gArdeN" should return 4.

User input

Task 3.1

Ask the user his/her name and then greet him/her with "Hello !".
Careful, only the first letter is capitalized, such as "Hello Archibald!".

Task 3.2

Prompt the user for a number.
Then, print the **type** of the provided input.

It should return `<class 'str'>`.
Can you understand what that means?

Task 3.3

Prompt the user for two numbers.
Then, print "The sum of the provided numbers is .".

For instance, the inputs `42` and `666` should return `708`.

Task 3.4

Write a program that:

- ✓ asks the user to type a string;

- ✓ extracts the first letter of each word in the string;
- ✓ joins these letters to make a word.

For instance, the input `Play your trumpet happily on nights.` returns `Python`.

Task 3.5

Write a program that counts the frequency of each letter from a given text and infers the language of this very text.

Task 3.6

Copy your previous program. Then, modify it to work with [UTF-8](#).

v 2.2

{EPITECH}
